Spans

Section Geometry

Tf = 200

Dtotal = 600

Width of Band = 1000

Width of Flange = 2000

40 MPa concrete

Loads

- 1- Self weight of beam = $(0.2 \times 2 + 0.4 \times 1) \times 25 = 20 \text{ KN/m'}$
- 2- SDL = 32 KN/m' (8 meters trib width and 4KPa) - highly loaded
- 3- LL = 48 KN/m' (8 meters trib width and 6 KPa) - highly loaded

PT Information

- 1- Balance some 80% of own weight, and
- 2- Minimise Deflection and
- 3- Minimise Flexural Reinforcement

Click on the cells in table above to insert / update the beam data

Educational Example Only – Refer to current Australian Standards and project-specific requirements before design.

First things first, we need to work out the actual magnitude of the load that we need to balance using the PT, there are so many scenarios and no 2 beams will be designed similarly, it depends on the software and experience.

in our case the beam's own weight is 20 KN/m, if we size up the PT to be equal to that, then the beam design will be effectively against the permanent SDL and LL loads.

When SDL and LL loads are high, these will trigger tension-compression stresses within the depth of the section (for example at mid span where we have sagging moments, tension will at bottom of section).

these tension stresses should be as low as possible, less than 1 MPa for example

Australian (and international standards) address the question of tension stresses in PT beams, for example the following screenshots from AS3600-2018 and concrete centre document

8.6.3 Crack control for flexure in prestressed beams

Flexural cracking in a prestressed beam shall be deemed to be controlled if, under the short-term service loads, the resulting maximum tensile stress in the concrete does not exceed $0.25\sqrt{f'_c}$ or, if this stress is exceeded, by providing reinforcement or bonded tendons, or both, near the tensile face with a centre-to-centre spacing not exceeding 300 mm and by either of the following:

- (a) Limiting the calculated maximum flexural tensile stress in the concrete under short-term service loads to $0.6\sqrt{f'_c}$.

or

- (b) Limiting the increment in steel stress near the tension face to that given in Table 8.6.3, as the load increases from its value when the extreme concrete tensile fibre is at zero stress to the short-term service load value.

or

- (c) Limiting the calculated maximum crack width in accordance with Clause 8.6.2.3.

TABLE 8.6.3

MAXIMUM INCREMENT OF STEEL STRESS
FOR FLEXURE IN PRESTRESSED BEAMS

Nominal reinforcement bar diameter (d_b) mm	Maximum increment of steel stress MPa
≤12	320
16	280
20	240
24	210
≥28	200
All bonded tendons	200

Table 3.17

Design flexural stresses for post-tensioned members (N/mm²) (Based on tables 4.1 to 4.3 of BS 8110)

		Concrete class		
		C25/30	C32/40	≥ C40/50
Compressive stresses				
In span and at cantilever supports		9.9	13.2	16.5
At support (except cantilevers)		12.0	16.0	20.0
Tensile stresses				
Class 1 ^a		0.0	0.0	0.0
Class 2 ^b		2.1	2.3	2.6
Class 3 ^c	Crack width (mm)			
	Member depth (mm)			

Key

a Class 1 serviceability condition does not allow flexural tensile stresses

b Class 2 serviceability condition allows flexural tensile stresses but no visible cracking

c Class 3 serviceability condition allows flexural tensile stresses with maximum crack width of 0.1 mm for exposure classes XS2, XS3, XD2, XD3, XF3 and XF4, otherwise a crack width of 0.2 mm may be used

so if we will have tension above $0.25\sqrt{f'_c}$ (1.54 MPa) then reinforcement will be required

Below screenshot is from PTKalc, see notes

Your Design Package is valid until 30/03/2030 10:44:38 PM

Profile is Valid

Initial try to balance the loads

Drag the drapes up and down, or left and right until you achieve circa 20kN/m' which is the weight of the beam

However need to note that small spans followed by longer ones do not make things perfect, and reality is that we must, normally, have parabolic profiles to get load distributed nicely. short span here at the start and nature of profile is dictating higher load than own weight, and this would result in secondary moment that are not favorable for moment diagrams.

Concordant profile (that triggers zero secondary moment) is not always possible in beams, unless it is a bridge with uniform section.

Materials & Criteria

amount of balancing load by PT

this is a key item, rupture stress, $0.6 \cdot f_c^{0.5}$ some people prefer to reduce this to 1 or 1.5 MPa, designer's call, impacts deflection

Maximum Inertia ratio (effective inertia), refer to clause 8.5.3.1 of AS3600-2018 the standard allows for full inertia to be used in case of prestressed beams with high P/A Would keep it at 0.6 (but again designers call)

Creep and shrinkage factors to be taken from Section 3 of AS3600-2018 these greatly impact long term deflection

This is the P/A try to keep it within 1.4 and up to 2.5 for extremely loaded beams. See section 8+9 of AS3600

This is the curvature of tendon, could be changed to 6 meters for example, but industry standard is 5 for thin slabs

Take this from Section 3 of AS3600-2018 also age of loading for deflection

Standard values

Now we need to read a load combination, which is DL+SDL+PT to understand what moments and stresses we have from PT and Own weight, this is important to establish how good is your system:

Bending Moments from Pure PT

Bending Moment Diagram - KN.m / PT

note the moments
we try to have these values
opposite to each other

Bending Moments from Own Weight

Combined Moments from OW+PT

Bending Moment Diagram - KN.m / LC-1.00W+1.0PT

To have a feel of how stressed is a beam, work out the ratio M/bd^2 , if this one is above say 2.5 to 4 then the beam is highly loaded,

in our case we have maximum of 31KN.m this is an $M/bd^2 = 31E+6/1000/550^2 = 0.1$ so the beam is almost at zero stress state :) or does not have tension,

Figure above shows the stress state of section, bottom stress blocks at mid span and over supports are all indicating compression, that is the ratio = $P/A + M/Z$

whereas the own weight stress block diagram looks like:

Load Case :

click on elastic stress block for the DL+PT case

now we can progress to review the bending moment diagram and stress block from ultimate load case, for example 1.2DL+1.5LL

Bending Moment Diagram - KN.m / LC-1.2DL+1.5LL

Shear Force Diagram - KN , m / LC-1.2DL+1.5LL

To gauge the section stress under PURE ultimate actions:

$$M/bd^2 = 900E+6 / 1000 / 550^2 = 3$$

(so the section is approaching high stress state)

$$\text{Shear Stress} = 650E3 / 1000 / 550 = 1.18 \text{ MPa}$$

(shear stress is not very high, would be concerned if its 3 or 4 MPa for example - case of transfer beams)

so if the beam is RC we would require

$$A_s = 900E+6 / (0.7 \cdot f_y \cdot 550) = 4700 \text{ mm}^2 \text{ (approx of 8N28)}$$

we have provided 3 x 2 x 15.2 strands (area of each is

143mm²), this is equal to

$$\text{equivalent normal reo} = 3 \times 2 \times 143 \times (0.82 \cdot 1800) / 500 = 2500$$

so we are short of circa 2000 mm² worth of rebar?

let us see next page

TENSILE STRENGTH OF COMMONLY US

Material type and Standard	Nominal diameter mm	Area mm ²
As-drawn wire, AS/NZS 4672.1	5.0	19.6
	7.0	38.5
Stress-relieved wire, AS/NZS 4672.1	5.0	19.9
	7.0	38.5
7 wire ordinary strand, AS/NZS 4672.1	9.5	55.0
	12.7	98.6
	15.2	143
	15.7	143
	15.7	150

here we need 1600mm²

here we need around 2500mm²
which is making sense!

Next is deflection check

Below diagram shows the deflection long term case under $DL+0.4LL+0.9PT$
this is all good, given the beam deflection = 19.6 mm at end span, but need to note that the slab sitting on this beam must not deflect more than say 25 in total (her deflection plus deflection of the beam itself) designer to make the call.

Deformations in grey are elastic without allowance for cracking (full section)
Deformations in red include effective section properties after cracking and creep

Deformations Diagram - Units: mm, Rad / LC-1.0DL+0.4LL+PT

You can study sensitivity of the beam, for example set the allowed tension at 1 MPa?

Deformations Diagram - Units: mm, Rad / LC-1.0DL+0.4LL+PT

or maybe change the loading age from 10 to 14 days?

Deformations Diagram - Units: mm, Rad / LC-1.0DL+0.4LL+PT

Can we for example reduce the reo at second span by increasing PT load?

PTKalc Analysis & Design Report

Concrete beam analysis and design to AS 3600:2018

Generated
11 August 2026, 6:51 PM

Prepared by
admin@rkalc.com

1. Report Overview

This report summarises the analysis and design of the beam in accordance with AS 3600:2018, including Amendment 2 where applicable.

The report includes load cases and combinations, member geometry, moment and shear results, deformation, flexural design and shear design.

The calculations are presented so that the adopted inputs and reported results can be independently reviewed.

2. Materials and Design Criteria

Criterion	Value
